

Meridional and Zonal Keograms – NESSie Imager

Temporal resolution: 10 s
Spatial resolution: 0.5 km
Pixel variable: OH emission intensity (arbitrary units)

Raw Imager Field-of-View

Meridional and zonal keograms are assembled from hydroxyl (OH) all-sky images taken from the Poker Flat Research Range (65 N, 147 W).

Images are taken from dusk to dawn at a 10 s cadence from September to April. Images are unwarped following Garcia et al., 1997 and cropped towards zenith to minimize fisheye distortion, resulting in a final processed image area of 600 x 600 km (1201 x 1201 pixels).

Keograms are produced by taking the center column (meridional component) or row (zonal component) from each image, using the image's capture time as the corresponding time index.

This data is publicly available. Users are encouraged to contact the PI (Dr. Katrina Bossert, keboss@asu.edu) regarding ongoing analyses, interpretations, and potential collaborations.
